

In dense environments like forests, collapsed buildings, or caves where GPS and Wi-Fi networks fail, autonomous micro-drones use bio-inspired "waggle" communication. They pass data packets and directional vector coordinates to one another visually or via localized radio frequencies to map areas collectively.

Feature	How Drone "Butt Shaking" Communication Works
Why Use It?	It allows drones to pass telemetry and location data to each other in radio-silent, jammed, or GPS-denied environments (like deep space, military electronic warfare zones, or collapsed disaster areas).
The Signal	A drone pitches or yaws rapidly back and forth in place ("shaking its tail"), or traces a physical shape on a plane while rapidly oscillating its chassis.
The Reception	A second drone captures the shaking motion using its onboard camera and processes the frequency, angle, and duration of the oscillation via computer vision algorithms to decode the target coordinates.
